

4-PYRROLIDINO-PHENYL-BENZYL ETHER DERIVATIVES

Field of the Invention

[0001] The present invention relates to new 4-pyrrolidino derivatives, to processes and intermediates for their preparation, and to pharmaceutical compositions containing them. These compounds are selective monoamine oxidase B inhibitors and, therefore, are useful for treating or preventing diseases mediated by monoamine oxidase B.

Background of the Invention

[0002] Monoamine oxidase (MAO, EC 1.4.3.4) is a flavin-containing enzyme responsible for the oxidative deamination of endogenous monoamine neurotransmitters such as dopamine, serotonin, adrenaline, or noradrenaline, and trace amines, e.g. phenylethylamine, as well as a number of amine xenobiotics. The enzyme exists in two forms, MAO-A and MAO-B, encoded by different genes [Bach et al., Proc. Natl. Acad. Sci. USA 85:4934-4938 (1988)] and differing in tissue distribution, structure and substrate specificity. MAO-A has higher affinity for serotonin, octopamine, adrenaline, and noradrenaline; whereas the natural substrates for MAO-B are phenylethylamine and tyramine. Dopamine is thought to be oxidised by both isoforms. MAO-B is widely distributed in several organs including brain [Cesura and Pletscher, Prog. Drug Research 38:171-297 (1992)]. Brain MAO-B activity appears to increase with age. This increase has been attributed to the gliosis associated with aging [Fowler et al., J. Neural. Transm. 49:1-20 (1980)]. Additionally, MAO-B activity is significantly higher in the brains of patients with Alzheimer's disease [Dostert et al., Biochem. Pharmacol. 38:555-561 (1989)] and it has been found to be highly expressed in astrocytes around senile plaques [Saura et al., Neuroscience 70:755-774 (1994)]. In this context, since oxidative deamination of primary monoamines by MAO produces NH_3 , aldehydes and H_2O_2 ,

agents with established or potential toxicity, it is suggested that there is a rationale for the use of selective MAO-B inhibitors for the treatment of dementia and Parkinson's disease. Inhibition of MAO-B causes a reduction in the enzymatic inactivation of dopamine and thus prolongation of the availability of the neurotransmitter in dopaminergic neurons. The degeneration processes associated with age and Alzheimer's and Parkinson's diseases may also be attributed to oxidative stress due to increased MAO activity and consequent increased formation of H₂O₂ by MAO-B.

[0003] Therefore, MAO-B inhibitors may act by both reducing the formation of oxygen radicals and elevating the levels of monoamines in the brain.

[0004] Given the implication of MAO-B in the neurological disorders mentioned above, there is considerable interest to obtain potent and selective inhibitors that would permit control over this enzymatic activity. The pharmacology of some known MAO-B inhibitors is for example discussed by Bentué-Ferrer et al. [CNS Drugs 6:217-236 (1996)]. Whereas a major limitation of irreversible and non-selective MAO inhibitor activity is the need to observe dietary precautions due to the risk of inducing a hypertensive crisis when dietary tyramine is ingested, as well as the potential for interactions with other medications [Gardner et al., J. Clin. Psychiatry 57:99-104 (1996)], these adverse events are of less concern with reversible and selective MAO inhibitors, in particular of MAO-B. Thus, there is a need for MAO-B inhibitors with a high selectivity and without the adverse side-effects typical of irreversible MAO inhibitors with low selectivity for the enzyme.

(c) R^4 is NHR^6

comprising reacting a compound of formula IV

wherein R^1 , $R^{1.1}$, $R^{1.2}$, R^{21} , R^{22} , R^{23} , R^{24} , R^3 , X and Y have the meanings as defined above, with an acyl donating agent of formula $Z-CO-(C_1-C_6)$ -alkyl, $Z-CO$ -halogen- (C_1-C_3) -alkyl, $Z-CO-O-(C_1-C_3)$ -alkyl, or $Z-SO_2-(C_1-C_3)$ -alkyl wherein Z is an activating group, e.g. a halogen or anhydride, or with an isocyanate.

[0050] The compounds of general formula I* can be manufactured by reacting a compound of formula II*

wherein R^1 , R^{21} , R^{22} , R^{23} , R^{24} and n have the above meanings

with an amine of formula H_2N-R^5 , wherein R^5 has the above meaning, to obtain a compound of formula Ia*

[0051] All starting materials employed in the processes described herein are either commercially available or can be prepared by conventional means.

[0052] In accordance with the present invention, scheme 1 shows exemplary routes to compounds of the formula I, all starting from a compound of formula V. The reaction of a compound of formula V with a compound of formula VI [Ikuta et al., J. Med. Chem. 30:1995 (1987)] to obtain the intermediate of formula IIIa, may be in inert solvents like dichloromethane, ethyl acetate or ethers in the presence of a base like triethylamine or carbonate and at a temperature in the range of from 0°C to 25°C. Cyclisation of the intermediate 2,4-dihalo-N-acyl derivative to the pyrrolidone IIIa may be with bases like sodium or potassium hydroxide in inert solvents like dichloromethane or ethers at a temperature of from 0°C to 25°C. Intermediates II wherein R* is H, i.e. compounds of formula IIa, are prepared by reacting a compound of formula V with 6,6-dimethyl-5,7-dioxaspiro[2,5]octane-4,8-dione VII, as described by Danishefsky et al. [J. Amer.Chem. Soc. 97:3239 (1975)].

Scheme 1

[0053] Another method to prepare compounds of formula I involves cross-coupling reactions of arylstannanes [Lam et al., Tetrahedron Lett. 43:3091 (2002)], arylboronates [Lam et al., Synlett 5:674 (2000); Chan et al., Tetrahedron Lett. 39:2933 (1998)] or aryl halides [Buchwald et al., J. Amer. Chem. Soc. 118:7215 (1996)] with the corresponding pyrrolidones (scheme 2).

Scheme 2

wherein LG is halogen, e.g. Cl, Br or I, or SnR_3 or $B(OH)_2$.

[0054] In accordance with the present invention, one method for preparing compounds of general formula **V**, wherein $-X-Y-$ is $-CH_2-O-$, i.e. compounds of formula **Va**, is shown in scheme 3: The intermediates of formula **XII** are accessible through nucleophilic

substitution of aromatic nitro compounds of formula XI containing p-substituted leaving groups with benzylic alcohols of formula X. Leaving groups in para-position can be, e.g., halogens (F, Cl, Br, I), tosylates, mesylates or triflates. These substitution reactions can be conducted neat or in inert solvents, for example, toluene or xylene. A preferred reaction temperature is in the range of from 50°C to 150°C. Alternatively, compounds of formula XII can be prepared by Williamson-ether synthesis, starting from p-nitrophenols XIV and benzylic halides, tosylates, mesylates or triflates of formula XIII. Bases used can be, e.g. alcoholates or carbonates (sodium, potassium or cesium carbonate). Examples for solvents include lower alcohols, acetonitrile or lower ketones at a temperature in the range of from 20°C to reflux temperature. Another approach is the Mitsunobu-coupling of benzylic alcohols with p-nitrophenols. The reaction is done as usual in inert solvents, for example, diethyl ether or tetrahydrofuran, using dialkyl-azo-dicarboxylates in the presence of phosphines (for example tributyl- or triphenyl-phosphine).

[0055] The key intermediates of formula XII are reduced to the amino compounds of formula Va using catalytic hydrogenation, e.g. using platinum on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofuran. An alternative is the reduction of the nitro-group by metals like iron, tin, or zinc in acidic media like diluted hydrochloric acid or acetic acid. Metals can also be replaced by metal salts, e.g., tin-(II)-chloride).

Scheme 3

wherein LG is a leaving group, e.g. halogen and OTf, or OH (for Mitsunobu-coupling).

[0056] In accordance with the present invention, intermediates of formula Vb (wherein –X–Y– is –CH=CH–) and Vc (wherein –X–Y– is –CH₂–CH₂–) can be prepared, for example, as shown in scheme 4: The intermediates of formula XVII are accessible by olefination reaction of optionally substituted aromatic aldehydes of formula XV with dialkyl (4-nitro-benzyl)-phosphonates of formula XVI in the presence of a base, e.g. sodium hydride, yielding the corresponding nitro-olefins of formula XVII.

Scheme 4

[0057] The key intermediates of formula XVII can be reduced selectively to the amino-olefins of formula Vb using catalytic hydrogenation, e.g., using platinum on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofurane as the solvent, or, by metals or metal salts, e.g., tin-(II)-chloride. The amino derivatives of formula Vc can be obtained directly from the nitro derivatives of formula XVII or from the amino-olefins of formula Vb by hydrogenation using palladium on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofurane as the solvent.

[0058] Intermediates II can be transformed into compounds of formula I using standard procedures. The acids II are activated via acid chloride (thionyl chloride or oxalyl chloride)

or with DCC, EDC etc. and subsequently coupled with the amine R^5-NH_2 . Alternatively, the corresponding alkylesters can be transformed to intermediates II by aminolysis by amines of formula R^5-NH_2 .

[0059] Intermediates III can be transformed into the desired compounds I wherein R^4 is CN, i.e. compounds of formula Ib, by reaction with sodium or potassium cyanide in solvents like N,N-dimethylformamide, acetone or acetonitrile at a temperature in the range of from 20°C to 140°C. Catalytic amounts of sodium or potassium iodide can be added to speed up the reaction (scheme 5).

Scheme 5

[0060] Compounds of formula IV can be obtained starting from acid derivatives of formula II by nucleophilic migrations from a carbon to a nitrogen atom, such as e.g. by Hofmann or Curtius rearrangement, via the formation of the corresponding isocyanate and its treatment with suitable alcohols delivering the protected amino group, methods known per se from the literature (scheme 6). For the treatment of the intermediate isocyanate, alcohols are selected which yield the typical carbamates used as amine protecting groups, such as e.g. tert-butoxycarbonyl, benzyloxycarbonyl, or fluorenylmethoxycarbonyl. Their cleavage to the amine follows the protocols which are well known in the literature. The further transformation to compounds of formula I can be performed by standard procedures, such as e.g. by reaction with activated acyl derivatives, e.g. acyl halogenides or anhydrides, or by condensation reactions of the acid using e.g. carbodiimides as condensation reagent, or by isocyanates.

Scheme 6

[0061] For the preparation of enantiopure derivatives of formula IV, an alternative route can be followed (scheme 7). Basically, the protocol follows the conditions described by Freidinger et al. [J. Org. Chem. 47:104-109 (1982)] where the aniline derivative of formula V is acylated by an N-protected methionine derivative in its racemic or optically active form by standard conditions of condensation reactions to give compounds of formula XIX. Methylation with methyl iodide or trimethyl-sulfonium or trimethylsulfoxonium salts and treatment of the resulting dimethyl-sulfonium salt with base, such as e.g. sodium hydride or lithium or potassium bis(trimethylsilyl)amide, in solvents inert under these conditions, e.g. THF, dichloromethane or N,N-dimethylformamide, yield the cyclised N-protected product of formula XX. Another variation of this cyclisation procedure is described in EP 985,665 which refers to a process for the preparation of 3-amino-2-oxo-pyrrolidines.

Scheme 7

[0062] In compounds of formula I or XX where -X-Y- has the meaning of -CH₂-O-, the optionally substituted benzyl residue can function as a transient group which can be cleaved by hydrogenolysis. The resulting phenols Id and XXa can then be re-alkylated by a different benzyl group under the aforementioned conditions. As known to those skilled in the art, this process is only possible on condition that R⁶ and PG are representing groups that are stable under the aforementioned reaction conditions for the hydrogenolysis and alkylation reaction, e.g. formyl or acetyl for R⁶, tert-butoxycarbonyl (BOC) for PG.

[0063] Compounds of general formula I can also exist in optically pure form. Such optically pure compounds can be prepared from enantiopure compounds from the chiral

pool, e.g., (R)- or (S)-methionine as already described for the preparation of enantiopure derivatives of formula IV (scheme 7). In other cases, separation into antipodes can be affected according methods known per se, either preferably at an early stage of the synthesis starting with compounds of formula II by salt formation with an optically active amine such as, for example, (+)- or (-)-1-phenylethylamine and separation of the diastereomeric salts by fractional crystallisation or preferably by derivatisation with a chiral auxiliary substance such as, for example, (+)- or (-)-2-butanol, (+)- or (-)-1-phenylethanol, or (+)- or (-)-menthol and separation of the diastereomeric products by chromatography and/or crystallisation and subsequent cleavage of the bond to the chiral auxiliary substance. In order to determine the absolute configuration of the pyrrolidinone derivative obtained, the pure diastereomeric salts and derivatives can be analysed by conventional spectroscopic methods, with X-ray spectroscopy on single crystals being an especially suitable method.

[0064] The Active Compounds are, as already mentioned above, monoamine oxidase B inhibitors and can be used for the treatment or prevention of diseases in which MAO-B inhibitors might be beneficial. These include acute and chronic neurological disorders, cognitive disorders and memory deficits. Treatable neurological disorders are for instance traumatic or chronic degenerative processes of the nervous system, such as Alzheimer's disease, other types of dementia, minimal cognitive impairment or Parkinson's disease.

[0065] Other indications include psychiatric diseases such as depression, anxiety, panic attack, social phobia, schizophrenia, eating and metabolic disorders such as obesity, as well as the prevention and treatment of withdrawal syndromes induced by abuse of alcohol, nicotine and other addictive drugs. Other treatable indications may be peripheral neuropathy caused by cancer chemotherapy (WO 97/33,572), reward deficiency syndrome (WO 01/34,172), or the treatment of multiple sclerosis (WO 96/40,095), and other neuroinflammatory diseases.

[0066] The Active Compounds are especially useful for the treatment and prevention of Alzheimer's disease and senile dementia.

[0067] The pharmacological activity of the compounds was tested using the following method:

[0068] The cDNAs encoding human MAO-A and MAO-B were transiently transfected into EBNA cells using the procedure described by Schlaeger and Christensen [Cytotechnology 15:1-13 (1998)]. After transfection, cells were homogenised by means of a Polytron homogenizer in 20 mM Tris HCl buffer, pH 8.0, containing 0.5 mM EGTA and 0.5 mM phenylmethanesulfonyl fluoride. Cell membranes were obtained by centrifugation at 45,000 x g and, after two rinsing steps with 20 mM Tris HCl buffer, pH 8.0, containing 0.5 mM EGTA, membranes were eventually re-suspended in the above buffer and aliquots stored at -80°C until use.

[0069] MAO-A and MAO-B enzymatic activity was assayed in 96-well-plates using a spectrophotometric assay adapted from the method described by Zhou and Panchuk-Voloshina [Analytical Biochemistry 253:169–174 (1997)]. Briefly, membrane aliquots were incubated in 0.1 M potassium phosphate buffer, pH 7.4, for 30 min at 37°C containing different concentrations of the compounds. After this period, the enzymatic reaction was started by the addition of the MAO substrate tyramine together with 1 U/ml horse-radish peroxidase (Roche Biochemicals) and 80 µM *N*-acetyl-3,7-dihydroxyphenoxazine (Amplex Red, Molecular Probes). The samples were further incubated for 30 min at 37°C in a final volume of 200 µl and absorbance was then determined at a wavelength of 570 nm using a SpectraMax plate reader (Molecular Devices). Background (non-specific) absorbance was determined in the presence of 10 µM clorgyline for MAO-A or 10 µM L-deprenyl for MAO-B. IC₅₀ values were determined from inhibition curves obtained using nine inhibitor concentrations in duplicate, by fitting data to a four parameter logistic equation using a computer program.

[0070] The compounds of the present invention are specific MAO-B inhibitors. The IC₅₀ values of preferred Active Compounds as measured in the assay described above are in the range of 1 μ M or less, typically 0.1 μ M or less, and ideally 0.02 μ M or less.

[0071] The present invention also provides pharmaceutical compositions containing Active Compounds, or pharmaceutically acceptable salts thereof, and a pharmaceutically acceptable carrier. Active Compounds includes individual isomers and racemic and non-racemic mixtures thereof. Such pharmaceutical compositions can be in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions. The pharmaceutical compositions can also be in the form of suppositories or injectable solutions.

[0072] The pharmaceutical compositions of the invention, in addition to one or more Active Compounds, contain a pharmaceutically acceptable carrier. Suitable pharmaceutically acceptable carriers include pharmaceutically inert, inorganic or organic carriers. Lactose, corn starch or derivatives thereof, talc, stearic acid or its salts and the like can be used, for example, as such carriers for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carriers for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi-solid and liquid polyols and the like; depending on the nature of the active substance no carriers are, however, usually required in the case of soft gelatine capsules. Suitable carriers for the production of solutions and syrups are, for example, water, polyols, sucrose, invert sugar, glucose and the like. Adjuvants, such as alcohols, polyols, glycerol, vegetable oils and the like, can be used for aqueous injection solutions of water-soluble salts of Active Compounds, but as a rule are not necessary. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

[0073] In addition, the pharmaceutical preparations can contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying

the osmotic pressure, buffers, masking agents or antioxidants. They may also contain other therapeutically valuable substances.

[0074] Compounds of the invention are selective MAO-B inhibitors. Therefore, the present invention also provides methods of treating or preventing diseases that are mediated by monoamine oxidase B. Such methods include administering a therapeutically effective amount of an Active Compound, for example, a compound of formula I or I*, or a pharmaceutically acceptable salt thereof, to an individual in need of such treatment. In one embodiment, the invention provides a method for the treatment or prevention of Alzheimer's disease by administering to an individual a therapeutically effective amount of an Active Compound, e.g., a compound of formula I or I*. In another embodiment, the present invention provides a method for the treatment or prevention of senile dementia by administering to an individual a therapeutically effective amount of an Active Compound, e.g., a compound of formula I or I*.

[0075] The compounds and compositions of the present invention can be administered in a conventional manner, for example, orally, rectally, or parenterally. The pharmaceutical compositions of the invention can be administered orally, for example, in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions, or suspensions. The pharmaceutical compositions also can be administered rectally, for example, in the form of suppositories, or parenterally, for example, in the form of injection solutions.

[0076] The dosage at which the Active Compound is administered can vary within wide limits and will, of course, be fitted to the individual requirements in each particular case. In general, the effective dosage for oral or parenteral administration is between 0.01-20 mg/kg/day, with a dosage of 0.1-10 mg/kg/day being preferred for all of the indications described. The daily dosage for an adult human being weighing 70 kg accordingly lies between 0.7-1400 mg per day, preferably between 7 and 700 mg per day.
